

JS Fundamentals

Credits : These are my notes from various JS Course : Javascript Mastery, Sheriyan coding school, Namaste JS : Akshay Saini

Socials :

- [Hardikk kamboj Twitter](#)
- [Hardikk Kamboj LinkedIn](#)

Variables

- Let - can be changed -> braces scoped -> cannot be added to window object
- const - constants in js - cannot be changed
- Var - can be changed (with some scope constraints) -> scope is inside function -> adds itself to window object
- Valid First characters for naming -> \$ or _
- Multiple same name vars cannot be there

Data Types

- String - single, double and backticks(``) quotes. - Can use JS in it - \${js inside here}
- Number - Number normal
- Null - null value (can be assigned)
- Undefined - no defined value (cannot be assigned)
- Typeof- to know the type of data type
- Object - group variables and store group of data types. `const object1={ name :'John', age:25,}` with dot notation to access the property.
- Array -> object

statically typed vs dynamically typed languages

js - dynamic - var can hold any data

c++ - statically typed

Operations

-> +, -, *, /
-> modulo - %
-> exponent - ** -> comparison < > (is equal) (true or false), !=(not equal), = (strict equals)`

Strict vs Loose equality

```
== VS ===  
5==5 -> true  
5 == "5" -> true  
5 === "5" -> false  
  
==== -> compares both values and Data types  
- true only when both are equal (Use it more )  
  
== -> Doesn't compare data types
```

Logical op

- AND && -> checks all and returns the last value (truthy) if false is encountered (return false value)
- OR || -> returns the first value (truthy) (returns the first true) and if false then the last false value
- NOT -> ! -> reverse bool value

TRUTHY VS FALSY

- 1, string, any other number, { }, []- truthy
- 0, null, false, '', Nan, Undefined -> falsy

Switch Statements

```
switch(value){  
case 'choice':  
    console.log("stiuff")  
    break;
```

```
default:  
    cosole.log("default value")  
}
```

Ternary Operator :

```
if(){  
}  
else if{  
}  
else{  
}
```

or

```
? : notation  
  
condition ? True : false
```

Loops

1. For loop - `for(let i=0; i<something; i++)`
2. While loop - `While(condition){
 what to do`

```
}
```

DRY PRINCIPAL -> DO Repeat Yourself

Functions

```
// Function declaration - defining  
// Function Call -> calling/executing the function  
  
function testing(parameter){  
    return parameter*parameter;  
}  
  
// call  
const result = testing(argument to be passed)  
  
result stores the value  
  
// Annonymous function  
  
const name = function(params){  
    // statements  
}  
  
// Arrow Functions  
  
const name = (params) => {  
    // statements  
}  
  
// Arrow with only one line
```

```
const name = (params) => params * params

// Function with defualt value

const add = (a=0,b=0) => {
return a + b;
}

const result = add(2);
```

Scope

- Where are the variables we make are available
- block, function and global scope

```
// Global scope

const name = 'john'

const logName = () => {
  console.log(name);
}

logName();

// Local Scope / function scope

const hey = () => {
  // Local to this function
  const name = 'phil'
  console.log(name);
```

```
}
```

Hoisting

- JS mechanism where variable and function declarations are moved to the top of their scope before code execution.

```
console.log(age);

var age = 20; // only the declarations goes to the top not the value;

--> undefined -> hoisting
```

case 2.

```
var hoist
console.log(hoist);
hoist = "something"

--> undefined ( hoisting )
```

case 3 :

```
function hoist(){
console.log(message);
var message = 'test';
}

hoist();
```

--> undefined

if function call is done first

```
hoist();
function hoist(){
var message = 'test';
console.log(message);

}

--> Test
Hoisting was done with function is time

// For consts and let variable
console.log(age);
const age = 25

--> error (no hoisting in modern js for consts and let)

hoist();
const hoist = () => {
console.log(message)
}

--> error
```

Closures

The screenshot shows a code editor window with a dark theme. The file tab at the top says "script.js". The code in the editor is:

```
// Closures in JavaScript
const outer = () => [
    const outerVar = 'Hello!';
    console.log(outerVar);
]
console.log(outerVar);
outer();
```

In the status bar at the bottom, there is a red error message: "Uncaught script.js:9 ReferenceError: outerVar is not defined at script.js:9".

- As soon as the function is done with the execution all of its content is gone, and that's why we cannot access the local scope var outside the function.
- Function inside a function

The screenshot shows a code editor window with a dark theme. The file tab at the top says "script.js". The code in the editor is:

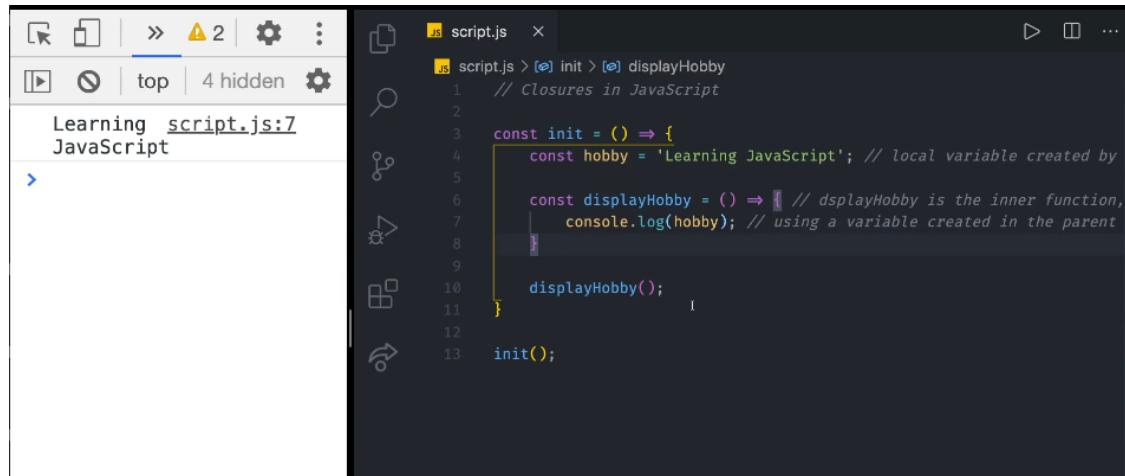

```
// Closures in JavaScript
const outer = () => {
    const outerVar = 'Hello!';
    const inner = () => {
        const innerVar = 'Hi!';
        console.log(outerVar, innerVar);
    }
    return inner;
}
const innerFn = outer();
innerFn();
```

In the status bar at the bottom, there is a yellow warning message: "Hello! Hi! script.js:9".

--> Access to the var of the parent scope : due to the closures.

-> that's why we get both Hi and Hello above

-> The inner data is not getting deleted here.

```
script.js
Learning script.js:7
JavaScript

const init = () => {
  const hobby = 'Learning JavaScript'; // local variable created by init()

  const displayHobby = () => { // displayHobby is the inner function, created by init()
    console.log(hobby); // using a variable created in the parent function
  }

  displayHobby();
}

init();
```

Strings

- types ' ', " ", ``
- property string.length, string[position], Cases : string.toLowerCase(), string.toUpperCase() -> store them in a new variable as well, String.indexOf('word') -> searches the first substring, save it to a var as well, string.includes('word')-> true or false
- Substring of a string - slice(start,end)
- Split a string into single chars -split method
string.split(' '); splits it on each character, word. -> turns into an array
- Reverse - reverse method works on arrays ->

First we turn the string into an array using the split method and then use reverse method to reverse the characters.

```
const reversed = string1.split("").reverse().join
```

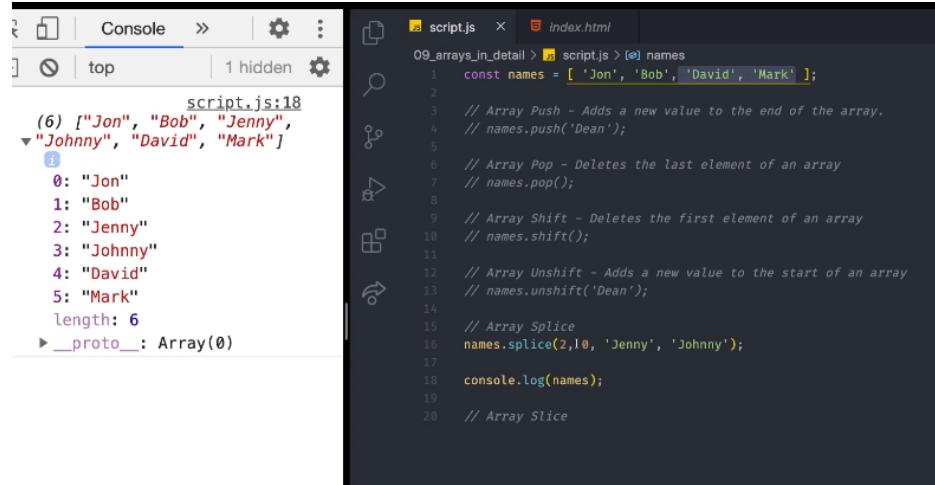

- String.trim() -> removes the spaces : used for storing emails.

Arrays

- Ordered Collection of Data
- const array = ['el1', 'el2'];

- loop over array -> for loop
- Array methods - push, pop, shift(remove first element of array), unshift(adds new value to the start of the array)
- Array Splice and Array Slice -

Splice -> array.splice(where to add, how many to remove, what all to add) : adds or remove and

```

script.js:18
(6) ["Jon", "Bob", "Jenny",
  "Johnny", "David", "Mark"]
  0: "Jon"
  1: "Bob"
  2: "Jenny"
  3: "Johnny"
  4: "David"
  5: "Mark"
  length: 6
  > __proto__: Array(0)

```

```

script.js:18
09_arrays_in_detail > script.js > names
1 const names = [ 'Jon', 'Bob', 'David', 'Mark' ];
2
3 // Array Push - Adds a new value to the end of the array.
4 // names.push('Dean');
5
6 // Array Pop - Deletes the last element of an array
7 // names.pop();
8
9 // Array Shift - Deletes the first element of an array
10 // names.shift();
11
12 // Array Unshift - Adds a new value to the start of an array
13 // names.unshift('Dean');
14
15 // Array Splice
16 names.splice(2,10, 'Jenny', 'Johnny');
17
18 console.log(names);
19
20 // Array Slice

```

Slice -> array.slice(start,end) ->copy certains parts of an array into a newly created array.

from (start to end) excluding end.

- Array For Each :

- easier way to write for loop
- Does not have a return value

```

array.forEach(value, index) => {
  console.log(value, index)
}

```

The screenshot shows a browser developer tools console with two tabs: 'script.js' and 'index.html'. The 'script.js' tab contains the following code:

```

const names = [ 'Jon', 'Jenny', 'Johnny' ];
names.forEach((name, i) => console.log(name, i));

```

The 'index.html' tab contains the following explanatory text:

```

// Use When
// you want to do something with each element of the array
// Don't use when
// you want to stop or break the loop when some condition is true
// you're working with async code

```

The bottom part of the screenshot shows another code block in 'script.js':

```

let sum = 0;
const numbers = [ 65, 44, 12, 4 ];

numbers.forEach((number) => {
  sum += number;
});

console.log(sum);

```

- Array map method :
- It allocates memory to store and return value (opposite to the for each method)
- Gives a new array all together

The screenshot shows a browser developer tools console with two tabs: 'script.js' and 'index.html'. The 'script.js' tab contains the following code:

```

const inventory = [
  { price: 5, name: 'eggs' },
  { price: 4, name: 'ham' },
  { price: 3, name: 'mayo' },
  { price: 5, name: 'bread' },
];
// Array Map
const prices = inventory.map(item => item.price);
const items = inventory.map(item => item.name);
console.log(items);

```

The output of the 'script.js' tab is shown in the 'index.html' tab:

```

(4) ["eggs", "ham", "mayo", "bread"]

```

- Array Filter method :
- It filters certain elements from an array.
- for ex- if you want only positive values
- Doesn't change the old array
- Returns a new array

The screenshot shows a browser developer tools console with two tabs: 'script.js' and 'index.html'. The 'script.js' tab contains the following code:

```

const numbers = [ -10, 0, -2, 15, -36, 25 ];
const positiveNumber = numbers.filter((number) => {
  return number >= 0;
});
console.log(positiveNumber);

```

The output of the 'script.js' tab is shown in the 'index.html' tab:

```

(3) [0, 15, 25]

```

- Real life ex -

```
// A start up wants to reward the employees
// with 7 or more hours of overtime

const employeesData = [
  { name: 'Sebastian', overtime: 5 },
  { name: 'Cardi Vee', overtime: 10 },
  { name: 'George Lopez', overtime: 12 }
];

const employeesToReward = employeesData.filter((employee) => employee.overtime >= 7);

console.log(employeesToReward);
```

- Array Find - returns the first value that satisfy the condition.

```
const numbers = [ 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 ];

const value = numbers.find((number) => number > 5);

console.log(value);

const states = [ 'Alaska', 'California', 'Colorado', 'Hawaii' ];

const state = states.find(state => state.startsWith('C'));

console.log(state);
```

- Array includes - checks if array includes something or not -> returns a Boolean value.

- It is case sensitive

```
const bookshelf = ["Moby Dick", "The Great Gatsby", "Pride and Prej

if(bookshelf.includes("Moby Dick")) {
  console.log('We have that book, here you go.');
} else {
  console.log('Cannot find the book, sorry!');
}
```

- Array Sort - sorts the array

- Modifies the same array
- `array.sort()`
- Ascending/ descending value

```
script.js:9
  1 // Array Sort
  2 // => alphabetically
  3 // => sorts numbers in ascending order
  4
  5 const numbers = [ 6, 3, 1, 7, 9, 2, 15, 25, 99, 44 ];
  6
  7 numbers.sort((a, b) => a - b);
  8
  9 console.log(numbers);
```

```
// Ascending Order  
// numbers.sort((a, b) => a - b);  
  
// Descending Order  
numbers.sort((a, b) => b - a);
```

- Array Some and Array Every

- Array Some - are some elements (checks a condition) and returns true or false.

```
const array = [1, 2, 3, 4, 5]  
  
// Array Some  
console.log(array.some((el) => el > 3)); // true
```

- Array Every - Check if every element is passing some condition

```
// Array Some => return true if at least one element passes the test  
console.log(array.some((el) => el > 3)); // true  
  
// Array Every => returns true only if all elements pass the test  
console.log(array.every((el) => el > 0)); // false
```

- Array Reduce - iterates over all the values and computes them to a single value
 - No need of an external var is there
 - Same example with forEach and reduce method
 - For each :

```
const groceryList = [ 29, 12, 45, 35, 87, 110 ];  
let total = 0;  
groceryList.forEach((price) => {  
    total += price;  
});  
console.log(total);
```

- Reduce :
 - Takes in 2 arguments and a callback-function value called accumulator
 - 0 is the initial value

```
const groceryList = [ 29, 12, 45, 35, 87, 110 ];  
  
const total = groceryList.reduce((accumulator, currentValue) => {  
    return accumulator + currentValue;  
}, 0);  
  
console.log(total);
```

```
const numbers = [ 1, 2, 3, 4, 5 ];

const sum = numbers.reduce((acc, val) => {
    return acc + val;
}, 0);

console.log(sum);

// acc = 0, val = 1 => 0 + 1 === 1; ← acc
// acc = 1, val = 2 => 1 + 2 === 3; ← acc
// acc = 3, val = 3 => 3 + 3 === 6; ← acc
// acc = 6, val = 4 => 6 + 4 === 10; ← acc
// acc = 10, val = 5 => 10 + 5 === 15
```

Objects

- Objects are unordered collection of related data
- In form of key-value pairs

```
const person = {
  firstName:'john'
  lastName: 'Doe'
  age: '40'
  car = {
    brand: 'maruti'
    year: 2016
    color: 'red'
  }
}
```

- Object Methods

- another property of an obj that is a function

```
const myObj = {
  myMethod: () => {
    },
  myMethod1: function() {
    },
  myMethod3() {
    }
}
```

```
const dog = [
  name: 'Fluffy',
  age: 2,
  listAllProperties: function() {
    console.log(this.name, this.age);
  }
]

dog.listAllProperties();
```

- Accessing - Adding and Updating object properties
 - Access - Use "DOT" notation
 - Add - use dot notation and { brackets } with key value pairs

```
// object is an unordered collection
// of related data
// in form of key and value pairs.

// DOT NOTATION
const person = {
  firstName: 'Brad',
}

person.dog = { name: 'Fluffy', age: 2 };
person.age = 25;

console.log(person.dog.name);
```

- Access using [Square Brackets] - can access properties dynamically.

```
// DOT NOTATION
const person = {
  firstName: 'Brad',
  age: 25,
}

const propertyI= 'age';

console.log(person.property);

// SQUARE BRACKET NOTATION

console.log(person[property]);
```

- Can access properties with dashes/ spaces using a string.

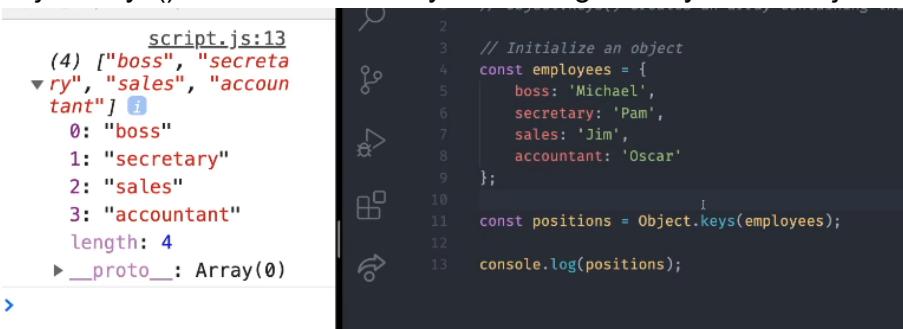

```
// DOT NOTATION
const person = [
  firstName: 'Brad',
  age: 25,
  "this is a key with spaces": true,
]

console.log(person.age);

// SQUARE BRACKET NOTATION
console.log(person['this is a key with spaces']);
```

- Built In Methods

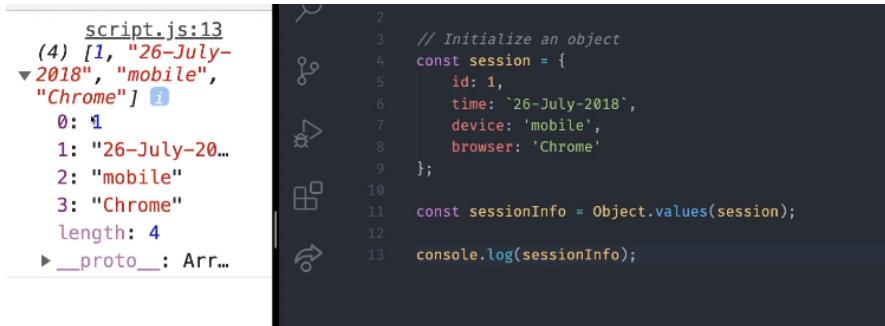

- object.keys() -> creates an array containing the keys of an object.

The screenshot shows a browser developer tools console. On the left, there is a tree-like structure showing the object's properties: 'script.js:13' has four children: 'boss', 'secretary', 'sales', and 'accountant'. Each of these has a numerical index (0, 1, 2, 3) and a value ('boss', 'secretary', 'sales', 'accountant'). Below this, there is a 'length' property with a value of 4, and a '__proto__' property pointing to 'Array(0)'. On the right, the code is displayed:

```
2 // Initialize an object
3 const employees = {
4   boss: 'Michael',
5   secretary: 'Pam',
6   sales: 'Jim',
7   accountant: 'Oscar'
8 };
9
10 const positions = Object.keys(employees);
11
12 console.log(positions);
13
```

- `Object.values()` : values of the keys

```

script.js:13
(4) [1, "26-July-2018", "mobile", "Chrome"]
  ▼ 0: 1
  1: "26-July-2018"
  2: "mobile"
  3: "Chrome"
  length: 4
  ▶ __proto__: Arr...

```

```

2 // Initialize an object
3 const session = {
4   id: 1,
5   time: '26-July-2018',
6   device: 'mobile',
7   browser: 'Chrome'
8 };
9
10 const sessionInfo = Object.values(session);
11
12 console.log(sessionInfo);
13

```

- `Object.entries()` : creates a nested array of key/value pairs of an object.

```

top | 1 hidden | settings
script.js:12
(3) [Array(2), Array(2), Array(2)]

```

```

1 // Object.entries() creates a nested array of the key/value pairs of
2
3 // Initialize an object
4 const operatingSystem = {
5   name: 'Ubuntu',
6   version: 18.04,
7   license: 'Open Source'
8 };
9
10 const entries = Object.entries(operatingSystem);
11
12 console.log(entries); | ...
13

```

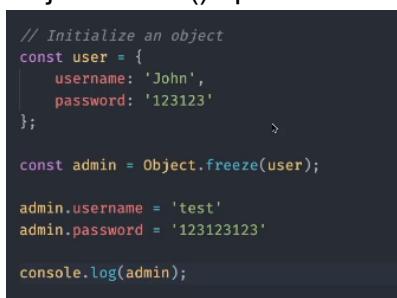

```

// Loop through the results
entries.forEach(entry => {
  let key = entry[0];
  let value = entry[1];

  console.log(`${key}: ${value}`);
});

```

- To display them all -
- `Object.freeze()` : prevents modification to properties and values of an object.

```

// Initialize an object
const user = {
  username: 'John',
  password: '123123'
};

const admin = Object.freeze(user);

admin.username = 'test'
admin.password = '123123123'

console.log(admin);

```

Values Vs Reference - Deep and Shallow Clone

- The concept comes in play when we are copying values
- For numbers

The image shows two side-by-side code snippets in a code editor. Both snippets illustrate how primitive values are copied by value.

Top Snippet:

```
1 // JavaScript differentiates Data Types on:  
2  
3 // - Primitive values (Number, String, Boolean...)  
4 // - Complex values (Objects, Arrays)  
5  
6 let x = 1; // 2  
7 let y = x; // 1  
8  
9 x = 2;  
10  
11 console.log(x);  
12 console.log(y);
```

Bottom Snippet:

```
1 // Javascript differentiates Data types on.  
2  
3 // - Primitive values (Number, String, Boolean... )  
4 // - Complex values (Objects, Arrays)  
5  
6 const animals = [ 'dogs', 'cats' ]; // [ 'dogs', 'cats' ]  
7 const otherAnimals = animals; // [ 'dogs', 'cats' ]  
8  
9 animals.push('llamas');  
10  
11 console.log(animals); // [ 'dogs', 'cats', 'llamas' ]  
12 console.log(otherAnimals); // [ 'dogs', 'cats' ]
```

- Complex values -

The image shows a code snippet in a code editor illustrating how objects are copied by reference.

```
1 // - Primitive values (Number, String, Boolean... )  
2 // - Complex values (Objects, Arrays)  
3  
4 // const animals = [ 'dogs', 'cats' ]; // [ 'dogs', 'cats' ]  
5 // const otherAnimals = animals; // [ 'dogs', 'cats' ]  
6  
7 // animals.push('llamas');  
8  
9 // console.log(animals); // [ 'dogs', 'cats', 'llamas' ]  
10 // console.log(otherAnimals); // [ 'dogs', 'cats' ]  
11  
12 const person = { firstName: 'Jon', lastName: 'Snow'  
13 const otherPerson = person;  
14  
15 (property) firstName: string  
16 person.firstName = 'Johnny';  
17  
18 console.log(person);  
19 console.log(otherPerson);
```

- why is it behaving like this in complex data types?

- when a variable is assigned a primitive value it just copies that value. (number and string) (copy by value)
- When a variable is assigned a non-primitive value (array, objects, functions) -> it is given an address to the location in the memory of that variable. (copied by reference -> location to memory)

```
false  script.js:14
1 // const otherPerson = person; // #123asd
2
3 // // PERSON AND OTHER PERSON POINT TO THE !SAME LOCATION
4
5 // person.firstName = 'Johnny';
6
7 // console.log(person);
8 // console.log(otherPerson);
9
10
11 const person = { name: 'Jon' };
12 const otherPerson = { name: 'Jon' };
13
14 console.log(person === otherPerson);
```

- Even if the values are equal they point to the different location in memory.

```
true  script.js:14
1 // const otherPerson = person; // #123asd
2
3 // // PERSON AND OTHER PERSON POINT TO THE !SAME LOCATION
4
5 // person.firstName = 'Johnny';
6
7 // console.log(person);
8 // console.log(otherPerson);
9
10
11 const person = { name: 'Jon' }; // #123asd
12 const otherPerson = person; // #123asd
13
14 console.log(person === otherPerson);
```

- Now they hold the same location in memory.

- Shallow Cloning :

- Cloning arrays

- Spread operator (...) -> get values individually

```
1 2 3 4 5 script.js:6
1 // 1st way. Spread operator
2
3 const numbers = [ 1, 2, 3, 4, 5 ];
4
5 console.log( ...numbers);|
```

```

true      script.js:8
false     script.js:9
▶
2 // 1st way: Spread Operator
3
4 const numbers = [ 1, 2, 3, 4, 5 ]; // #123asd
5 const copiedNumbers = numbers; // #123asd
6 const newNumbers = [ ...numbers ];
7
8 console.log(numbers === copiedNumbers);
9 console.log(numbers === newNumbers);

```

- In the second image 2 copies are created, first is equal as they point to same location in memory.
- Newnumber array is not pointing to the same location, as they represent 2 different arrays.

```

script.js:10
▶ (6) [1, 2, 3, 4, 5, 6]
script.js:11
▶ (6) [1, 2, 3, 4, 5, 6]
script.js:12
▶ (5) [1, 2, 3, 4, 5]
▶
2 // 2nd way: Spread Operator
3
4 const numbers = [ 1, 2, 3, 4, 5 ]; // #123asd
5 const copiedNumbers = numbers; // #123asd
6 const newNumbers = [ ...numbers ];
7
8 numbers.push(6);
9
10 console.log(numbers);
11 console.log(copiedNumbers);
12 console.log(newNumbers);

```

- The Newly created array using the spread operator remains unchanged, meaning it is a shallow clone.
- Array.slice () -> also creates a shallow clone -> creates a completely diffrent array pointing to a different location in memory.

```

script.js:9
▶ (6) [1, 2, 3, 4, 5, 6]
script.js:10
▶ (6) [1, 2, 3, 4, 5, 6]
script.js:11
▶ (5) [1, 2, 3, 4, 5]
▶
2 // 2nd way: Array.slice()
3
4 const numbers = [ 1, 2, 3, 4, 5 ]; // #123asd
5 const copiedNumbers = numbers; // #123asd
6 const newNumbers = numbers.slice(); // #321dsa
7
8 numbers.push(6);
9
10 console.log(numbers);
11 console.log(copiedNumbers);
12 console.log(newNumbers);

```

• Cloning Objects :

- Spread operator (...)

```

▶ {name: "John", age: 22}
script.js:9
▶ {name: "John", age: 20}
▶
3
4 const person = { name: "John", age: 20 };
5 const otherPerson = { ...person };
6
7 person.age = 22;
8
9 console.log(person);
10 console.log(otherPerson);

```

- Object.assign({new object}, og object)

```

script.js:8
▶ {name: "John", age: 22}
script.js:9
▶ {name: "John", age: 20}

```

```

2 // 2nd way: Object.assign()
3 const person = { name: "John", age: 20 };
4 const otherPerson = Object.assign({}, person);
5
6 person.age = 22;
7
8 console.log(person);
9 console.log(otherPerson);

```

- Deep Cloning :

- Issue with Shallow :

```

script.js:15
▼ {brand: "BMW", color: "blue",
wheels: 4} ⓘ
  brand: "BMW"
  color: "blue"
  wheels: 4
  ▶ __proto__: Object
script.js:16
▼ {brand: "BMW", color: "red",
wheels: 4} ⓘ
  brand: "BMW"
  color: "red"
  wheels: 4
  ▶ __proto__: Object

```

```

11_value_vs_reference > script.js > [o] person > ⚡ car
1 const person = {
2   firstName: 'Emma',
3   car: [
4     {
5       brand: 'BMW',
6       color: 'blue',
7       wheels: 4
8     }
9   ]
10 const newPerson = { ...person, car: { ...person.car } };
11
12 newPerson.firstName = 'Mia';
13 newPerson.car.color = 'red';
14
15 console.log(person.car);
16 console.log(newPerson.car);

```

- If the car color, which is an object inside an object has to be changed, the spread operator will just keep on increasing, as we have to mention the car obj as well in the spread operator for it to work, otherwise the car color will not change as the location we passed is only for the outer parent obj.
- Solution : This is for deeply nested obj we need a deep clone, for an obj to be a deep clone it needs to destroy all the references.
 - JSON.stringify() : Converts all the JS obj into string, thereby all the references are destroyed.

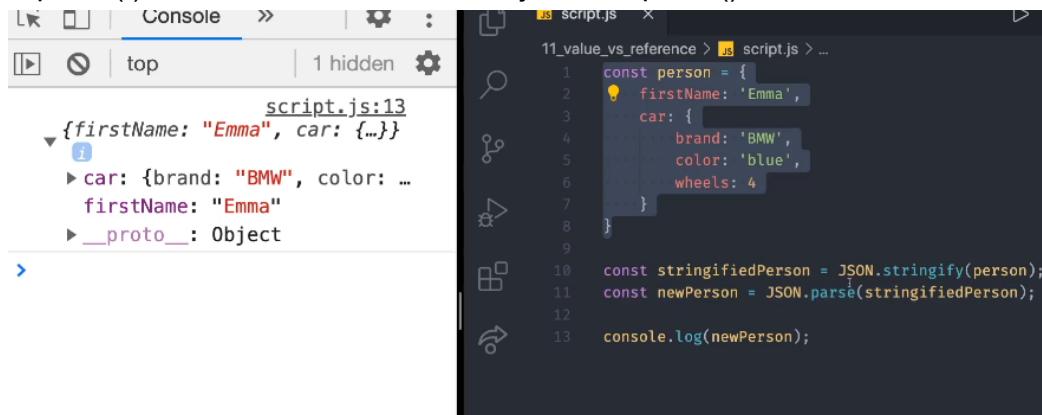

A screenshot of a browser developer tools console. The code being run is:

```
const person = {  
  firstName: 'Emma',  
  car: {  
    brand: 'BMW',  
    color: 'blue',  
    wheels: 4  
  }  
}  
  
const stringifiedPerson = JSON.stringify(person);  
  
console.log(stringifiedPerson);
```

The output in the console is:

```
{"firstName": "Emma", "car": {"brand": "BMW", "color": "blue", "wheels": 4}}
```

- `JSON.parse()` : to turn it back into a an obj we use `parse()`

A screenshot of a browser developer tools console. The code being run is:

```
const person = {  
  firstName: 'Emma',  
  car: {  
    brand: 'BMW',  
    color: 'blue',  
    wheels: 4  
  }  
}  
  
const stringifiedPerson = JSON.stringify(person);  
const newPerson = JSON.parse(stringifiedPerson);  
  
console.log(newPerson);
```

The output in the console is:

```
{firstName: "Emma", car: {brand: "BMW", color: "blue", wheels: 4}}
```

It is an obj but an obj that is the deep clone of the persons obj.

- Shortcut

```
const newPerson = JSON.parse(JSON.stringify(person));
```

- Result : deep cloning

```
2   firstName: 'Emma',
3   car: {
4     brand: 'BMW',
5     color: 'blue',
6     wheels: 4
7   }
8 }
9
10 const newPerson = JSON.parse(JSON.stringify(person));
11
12 newPerson.firstName = 'Mia';
13 newPerson.car.color = 'red';
14
15 console.log(person);
16 console.log(newPerson);
```

DOM : Document object model

- Accessing the elements in our html, via Javascript using certain methods :
 - `document.getElementById()` - get the elements by the id name
 - `document.getElementsByTagName('h1')` - returns all the elements by that tag
 - `document.getElementsByClassName('h1')` - same but with classname
 - `document.querySelectorAll('h2.classname')` : returns all the h2 with classname "what ever the classname is"
 - can use # to target ids, . to target classnames or just Tagname to target any tagname.

- Element Properties -

```
> const el = document.querySelector("#heading");
< undefined
> el
<-- <h1 class="test abc test1" id="heading">TEST
</h1>

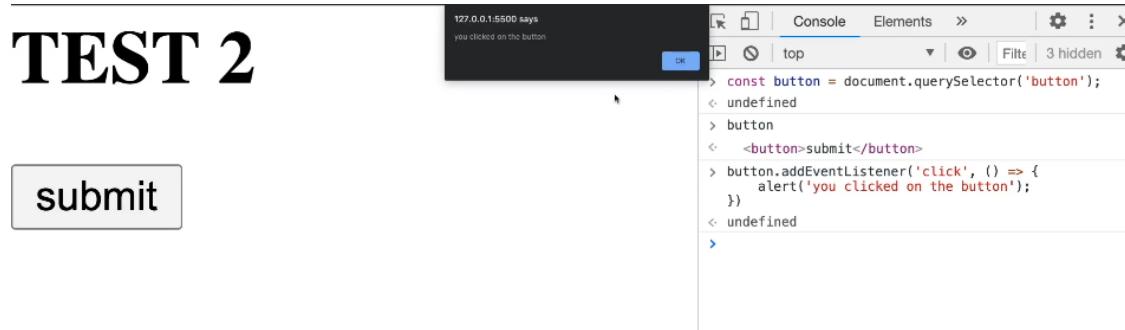

> el.classList
<-- DOMTokenList(3) ["test", "abc", "test1", value:
  "test abc test1"]

> el.className
<-- "test abc test1"

> el.id
<-- "heading"

> el.innerHTML
<-- "TEST"
```

- Methods :
 - addEventListener

- `getBoundingClientRect()`

```

> button.getBoundingClientRect()
< f getBoundingClientRect() { [native code] }
> button.getBoundingClientRect();
< DOMRect {x: 0, y: 174.1428680419922, width: 55.2
< 67860412597656, height: 21.428571701049805, top:
174.1428680419922, ...} ⓘ
  bottom: 195.51439743042
  height: 21.428571701049805
  left: 0
  right: 55.267860412597656
  top: 174.1428680419922
  width: 55.267860412597656
  x: 0
  y: 174.1428680419922
> __proto__: DOMRect

```

- `hasAttribute()`

```

> const button = document.querySelector('button');
< undefined
> button.hasAttribute('type');
< true
> button.removeAttribute('type');
< undefined
> button.hasAttribute('type');
< false
> |

```

Classes in DOM :

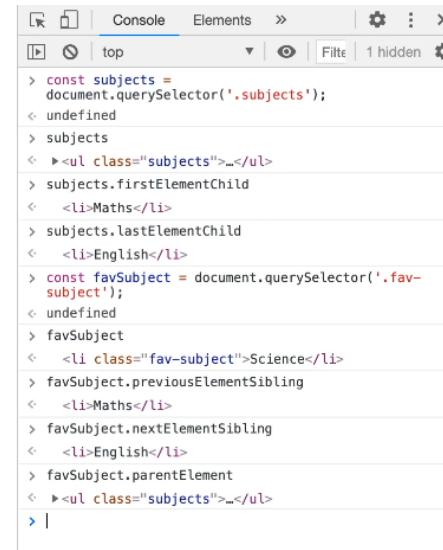

![[Pasted image 20231202101009.png]]

- Creating Nodes

- `document.createElement("h1")`
- `appendChild()` : to add it to the dom

- InnerText : to add the text to that created element
- InnerHtml : To add html to that element
- Traversing :

- Maths
- Science
- English

```

> const subjects =
< document.querySelector('.subjects');
< undefined
> subjects
< ><ul class="subjects">...</ul>
> subjects.firstElementChild
< <li>Maths</li>
> subjects.lastElementChild
< <li>English</li>
> const favSubject = document.querySelector('.fav-
< subject');
< undefined
> favSubject
< <li class="fav-subject">Science</li>
> favSubject.previousElementSibling
< <li>Maths</li>
> favSubject.nextElementSibling
< <li>English</li>
> favSubject.parentElement
< ><ul class="subjects">...</ul>
> |

```

- Removing :

```

> favSubject.remove();
< undefined

```

New Keyword

- Functionality : Creates a new empty object
- differences with normal way of creating it

```

script.js:12
Person {name: "John", age: 23,
profession: "Teacher"} ⓘ
  age: 23
  name: "John"
  profession: "Teacher"
  ► __proto__: Object
2 // It creates a new object.
3 const person = {};
4 const person1 = new Object();
5
6 person.firstName = 'John';
7 person1.firstName = 'John';
8
9 console.log(person);
10 console.log(person1);
11

```

- For just normal creation it is not used that much.
- Uses?
 - Can use a lot of properties of present objs as everything in JS is an Obj.

```
// It creates a new object.
const myNumber = new Number(100.234);

console.log(myNumber.toFixed(0));
```

- Dates

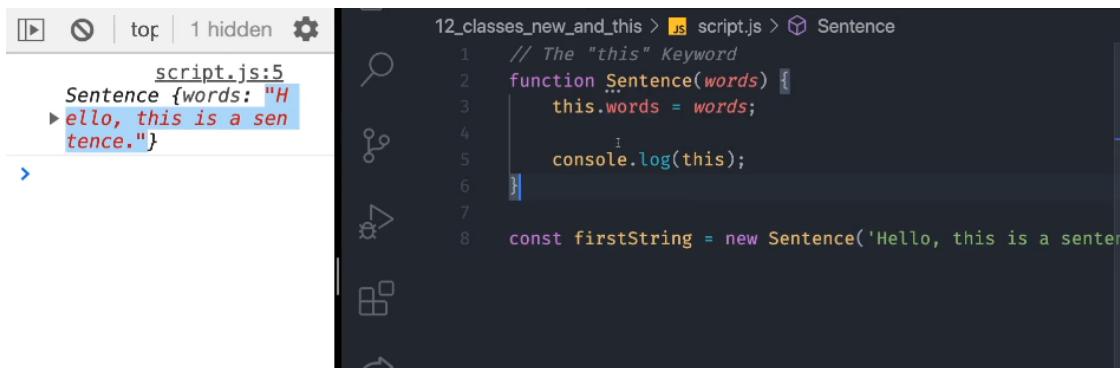

The screenshot shows a code editor window with a dark theme. On the left, there's a sidebar with icons for search, file navigation, and other functions. The main area shows a file named 'script.js' with the following code:

```
2025 // The "new" Keyword
script.js:6
1 // It creates a new object.
2 const myDate = new Date('August 11, 2025');
3
4 console.log(myDate.getFullYear());
5
6
7
```

- This date methods are extended of a different object.

This Keyword

- Used to reference the obj that is executing the current function.
- Every function has a reference to it, in its current execution context.
- Cannot use in arrow function

The screenshot shows the 'Sources' tab of a browser developer tools interface. It displays a file named 'script.js' with the following code:

```
12_classes_new_and_this > script.js > Sentence
script.js:5
1 // The "this" Keyword
2 function Sentence(words) {
3   this.words = words;
4
5   console.log(this);
6
7
8 const firstString = new Sentence('Hello, this is a sentence.');

```

The word 'this' is highlighted in red, indicating it is being analyzed by the tool. The status bar at the top shows '1 hidden'.

- This keyword points to a specific object
 - Without any function : references to the window object

A screenshot of a browser developer tools console. The code being run is:

```
script.js:2
Window {parent: Window, opener: null,
▶ top: Window, length: 0, frames: Window,
  w, ...}
```

The output shows the value of 'this' as the global window object.

- Inside a function : Refers to the Object 'this' keyword in

A screenshot of a browser developer tools console. The code being run is:

```
script.js:5
const person = {
  name: 'John',
  getName() {
    console.log(this);
  }
}
person.getName();
```

The output shows the value of 'this' inside the getName() function, which is the person object.

- Example :

A screenshot of a browser developer tools console. The code being run is:

```
script.js:7
function Car(color, brand, wheels) {
  this.color = color;
  this.brand = brand;
  this.wheels = wheels;
}
console.log(this);

const blueCar = new Car('blue', 'BMW', 4);
const redCar = new Car('red', 'Ferrari', 4);
```

The output shows the value of 'this' inside the constructor function, which is a new Car object.

Classes

- It is SCHEMA for an obj that can save many values
- Constructor is just like parameters in a function (keys are passed inside)

- Initiating a user for that class

```

script.js:11
Person {name: "Melissa", ag
e: 24, isWorking: true} ⓘ
age: 24,
isWorking: true
name: "Melissa"
▶ __proto__: Object

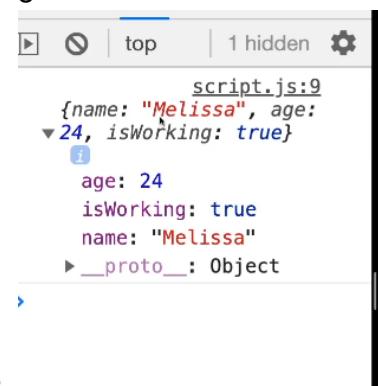

```

```

1 class Person {
2   constructor(name, age, isWorking) {
3     this.name = name;
4     this.age = age;
5     this.isWorking = isWorking;
6   }
7 }
8
9 const user = new Person('Melissa', 24, true);
10
11 console.log(user);

```

- Using Normal Functions

```

script.js:9
{name: "Melissa", age:
24, isWorking: true} ⓘ
age: 24
isWorking: true
name: "Melissa"
▶ __proto__: Object

```

```

12_classes_new_and_this > script.js > ...
1 const createPerson = (name, age, isWorking) => {
2   const userSchema = { name, age, isWorking }
3
4   return userSchema;
5 }
6
7 const user = createPerson('Melissa', 24, true);
8
9 console.log(user);

```

Intervals and Timers

- setInterval() -> 1000 is 1 second (counted in miliseconds)
- clearInterval() -> clears the interval once it is done

```

// setInterval
// clearInterval
const myInterval = setInterval(() => console.log('Hello, World!'), 1000);

• clearInterval(myInterval); ⏴

```

- setTimeout : -> wait certain amount of time before executing a chunk of code

- clearTimeout : ->

```
// setTimeout
// clearTimeout
const myInterval = setTimeout(() => console.log('Hello, World!'), 5000);

clearTimeout(myInterval);
```

- Asynchronous Nature :

13_asynchronous.js > script.js > ...

```
1  setTimeout(() => console.log('Hello, World at the top'), 5000);
2
3  console.log('Hello, World at the bottom');
```

Asynchronous JavaScript

- Synchronous : code is executed Line by Line and tasks are completed instantly.
 - There is no Time delay in the completion of the tasks for those lines of code.

13_asynchronous.js > script.js > functionOne

```
1 // Synchronous JS Example
2
3 const functionOne = () => {
4   console.log('Function One');
5
6   functionTwo();
7
8   console.log('Function One, Part 2')
9 }
10
11 const functionTwo = () => {
12   console.log('Function Two');
13 }
14
15 functionOne();
16
17 // 1
18 // 2
19 // 3
```

- Example :
- Asynchronous :
- Using the same example showing Async code:

A screenshot of a browser's developer tools console. The title bar shows "13_asynchronous_js > script.js > [e] functionTwo". The code editor contains the following JavaScript:

```
// Asynchronous JS Example
const functionOne = () => {
    console.log('Function One');
    functionTwo();
    console.log('Function One, Part 2')
}
const functionTwo = () => {
    setTimeout(() => console.log('Function Two'), 2000);
}
functionOne();
```

- Here the code takes some time to run. These tasks are run in the background while the JS engine keeps executing other lines of code. When the result of the waiting gets available, it is then used in the program.
- This happens because of something known as Event Loop.

Callbacks

- Data Fetching from API : Async : cannot be sure how long it will take

- Sync :

```
const fetchUser = (username) => [
    return { user: username };
]
```

- Async :

A screenshot of a browser's developer tools console. The title bar shows "13_asynchronous_js > script.js > ...". A red error message box is visible on the left, stating "Uncaught TypeError: script.js:9 Cannot read property 'username' of undefined at script.js:9". The code editor contains the following JavaScript:

```
const fetchUser = (username) => {
    setTimeout(() => {
        return { username };
    }, 2000);
}
const user = fetchUser('Michael');
console.log(`Your name is: ${user.username}`);
```

- The error is there because the data was not returned from the function immediately, but after 2 secs.
- To make it work we use Callback () functions.
- pass in a callback function which will run when the data is fetched
- After 2 secs we get

```

13_asynchronous_js > script.js > fetchUser
1 const fetchUser = (username, callback) => [
2   console.log('Fetching ... ');
3
4   setTimeout(() => {
5     console.log('Now we have the user.');
6
7     callback({ username });
8   }, 2000);
9
10
11 fetchUser('Michael', (user) => {
12   console.log(`Your name is: ${user.username}`);
13 });
14

```

Callback HELL

- A normal callback functionality looks like :

```

13_asynchronous_js > script.js > ...
1 const fetchUser = (username, callback) => [
2   setTimeout(() => {
3     callback({ username });
4   }, 2000);
5
6
7 fetchUser('Michael', (user) => {
8   console.log(`Your name is: ${user.username}`);
9 });
10

```

- We will replace callbacks with promises and async await due to the callback hell.
- A complicated functionality of callbacks - ex of social media app

```

[Now we have the user] script.js:3
Your name is: Michael script.js:18
[Now we have the photos script.js:11
for Michael]
Your photos are: Photo 1,Photo 2 script.js:21

13_asynchronous.js > js script.js > [e] fetchUserPhotos > setTimeout() ca
      5   |   callback({ username });
      6   |   }, 2000);
      7   |
      8
      9 const fetchUserPhotos = (username, callback) => {
     10   setTimeout(() => {
     11     console.log(`[Now we have the photos for ${use
     12
     13     callback(['Photo 1', 'Photo 2']);
     14   }, 2000);
     15 }
     16
     17 fetchUser('Michael', (user) => {
     18   console.log(`Your name is: ${user.username}`);
     19
     20   fetchUserPhotos(user.username, (userPhotos) => {
     21     console.log(`Your photos are: ${userPhotos}`);
     22   });
     23 });

```

- Now as the functionality grows it becomes a lot of code to do the same functionality that is called a **CALLBACK HELL!!!**

```

13_asynchronous.js > js script.js > ...
      25 // The Callback Hell
      26 fetchUser('Michael', (user) => {
      27   fetchUserPhotos(user.username, (userPhotos) => {
      28     fetchPhotoDetails(userPhotos[0], (details) => {
      29       fetchPhotoDetails(userPhotos[0], (detail) => {
      30         fetchPhotoDetails(userPhotos[0], (de
      31         fetchPhotoDetails(userPhotos[0], (det
      32         fetchPhotoDetails(userPhotos[0], (det
      33         fetchPhotoDetails(userPhotos[0], (det
      34         fetchPhotoDetails(userPhotos[0], (det
      35         fetchPhotoDetails(userPhotos[0], (det
      36         fetchPhotoDetails(userPhotos[0], (det
      37         fetchPhotoDetails(userPhotos[0], (det
      38         fetchPhotoDetails(userPhotos[0], (det
      39         fetchPhotoDetails(userPhotos[0], (det
      40         fetchPhotoDetails(userPhotos[0], (det
      41         fetchPhotoDetails(userPhotos[0], (det
      42         fetchPhotoDetails(userPhotos[0], (det
      43         });
      44       });
      45     });
      46   });
      47 });

```

- This is not maintainable and also not DRY (do not repeat yourself)
- To solve this issue Promises were introduced.

Promises

- They are objects that either return the successfully fetched data, or the error.
- It has two parameters resolve and reject
- Then keyword is used to invoke it, catch () to get the error

- Using the callback hell example

```
// Promises
const fetchUser = new Promise((resolve, reject) => {
  setTimeout(() => {
    console.log('[Now we have the user]');
    resolve({ username: 'Michael' });
  }, 2000);
});

fetchUser.then((user) => console.log(user.username));

settimeout(() => {
  console.log('[Now we have the user]');
  reject('User not found');
  // resolve({ username: 'Michael' });
}, 2000);

fetchUser
  .then((user) => console.log(user.username))
  .catch((error) => console.log(error));
```

- Multiple Promises

```
    resolve({ username });
  }, 2000);
};

const fetchUserPhotos = (username) => {
  return new Promise((resolve, reject) => {
    setTimeout(() => {
      console.log(`[Now we have the photos for ${username}`);
      resolve(['Photo 1', 'Photo 2']);
    }, 2000);
  });
}

const fetchPhotoDetails = (photo) => {
  return new Promise((resolve, reject) => {
    setTimeout(() => {
      console.log(`[Now we have the photo details for ${photo}`);
```

- The calling will be changed as :

The screenshot shows a browser developer tools console with the title "13_asynchronous_js > script.js > then() callback". The console output pane displays the following log messages:

```
[Now we have the user] script.js:4
[Now we have the photos script.js:14
for Michael]
[Now we have the photo script.js:24
details for the photo Photo 1]
Your photo details are: script.js:43
Details...
```

The code pane shows the following JavaScript code:

```
28     })
29   }
30
31   // NOT USING THIS => CALLBACK
32   // fetchUser('Michael', (user) => {
33   //   fetchUserPhotos(user.username, (userPhotos) => {
34   //     fetchPhotoDetails(userPhotos[0], (details) =>
35   //       console.log(`Your photo details are: ${de
36   //     });
37   //   );
38   // });
39
40   fetchUser('Michael')
41   .then((user) => fetchUserPhotos(user.username))
42   .then((photos) => fetchPhotoDetails(photos[0]))
43   .then((details) => console.log(`Your photo details a
44
```

Async () Await ()

- It is an easier and a cleaner way to work with promises
- They look like sync functions so they are easier to write
- Async functions returns promises

The screenshot shows a browser developer tools console with the title "script.js:54" and subtitle "Promise {<fulfilled>: 25} >". The console output pane displays the following log message:

```
Promise {<fulfilled>: 25}
```

The code pane shows the following JavaScript code:

```
45   //   .then((photos) => fetchPhotoDetails(pr
46   //   .then((details) => console.log(`Your p
47
48   // ASYNC FUNCTIONS RETURN PROMISES!!!
49
50   const fetchNumber = async () => {
51     return 25;
52   }
53
54   console.log(fetchNumber());
```

```
25      script.js:55
>      ↴
    46  //     .then((details) => console.log(`Your photo
    47
    48 // ASYNC FUNCTIONS RETURN PROMISES!!!
    49
    50 const fetchNumber = async () => {
    51   return 25;
    52 }
    53
    54 fetchNumber()
    55   .then((number) => console.log(number));

```

- Await Keyword : Waits for the promises to return a result.
 - If you want you use await it needs to be inside an async function
 - This is good as we do not have to use then() or fetch()

```
25      script.js:56
>      ↴
    46  //     .then((details) => console.log(`Your photo de
    47
    48 // ASYNC FUNCTIONS RETURN PROMISES!!!
    49
    50 // ASYNC => AWAIT
    51 const [fetchNumber] = async () => {
    52   return 25;
    53 }
    54
    55 const consoleFetchedNumber = async () => {
    56   console.log(await [fetchNumber()]);
    57 }
    58
    59 consoleFetchedNumber();

```

- Using the callback hell example

[Now we have the user]
[Now we have the photos for Michael]
[Now we have the photo details for the photo Photo 1]
Details.. script.js:50

```
37 //      });
38 //  });
39
40 // fetchUser('Michael')
41 //   .then((user) => fetchUserPhotos(user.username))
42 //   .then((photos) => fetchPhotoDetails(photos[0]))
43 //   .then((details) => console.log(`Your photo detail
44
45 const displayData = async () => {
46   const user = await fetchUser('Michael');
47   const photos = await fetchUserPhotos(user.username);
48   const details = await fetchPhotoDetails(photos[0]);
49
50   console.log(details);
51 }
52
53 displayData();
```

Import and Export

- To export one thing from a file
 - export default name
- To Import that thing from that file
 - import name from 'path'
- Add type = module in html src

```
<body>
  <script type="module" src="script.js">
</body>
```

- Example

```
My script.js:4
dogs are:
Bear,Fluffy,Dog
go
```

```
1 // IMPORTS AND EXPORTS
2 import dogs from './dogs.js';
3
4 console.log(`My dogs are: ${dogs}`);
```

```
1 const dogs = [ 'Bear', 'Fluffy', 'Dog'];
2
3 export default dogs;
```

- To export and import multiple things out of one file
- Add export keyword before all the things

- In Import use {} and add names of things you want to import

```

export const dogs = ['Bear', 'Fluffy', 'Doggie'];
export const numberOfDogs = dogs.length;

// IMPORTS AND EXPORTS
import { dogs, numberOfDogs } from './dogs.js';
import onlyOneThing from './test.js';

console.log(onlyOneThing);
|           I
console.log(`I have ${numberOfDogs} dogs`);
console.log('My dogs are: ${dogs}`);

```

- In import you can change the name of the import as well but it is not good practice

```

// IMPORTS AND EXPORTS
import { dogs, numberOfDogs } from './dogs.js';
import abc from './test.js';

console.log(abc);

```

Extras

- Object and array Destructuring

- Before : An object with Multiple values has been created, this is DRY

```

}
// DRY
console.log(person.firstName);
console.log(person.lastName);
console.log(person.car.color);
console.log(person.car.wheels);
console.log(person.car.wheels);
console.log(person.animals.dog.name);
console.log(person.animals.dog.age);
console.log(person.animals.cat.name);
console.log(person.animals.cat.age);

```

- After : Using Destructuring

```

const { firstName, lastName, car, animals } = person;

console.log(firstName);
console.log(lastName);
console.log(car.color);
console.log(car.wheels);
console.log(car.wheels);
console.log(animals.dog.name);
console.log(animals.dog.age);
console.log(animals.cat.name);
console.log(animals.cat.age);

```

- For internal properties

```
const { firstName, lastName, car: { color, wheels }, animals } = person;
console.log( const lastName: string
console.log(lastName);
console.log(color);
console.log(wheels);
console.log(animals.dog.name);
console.log(animals.dog.age);
console.log(animals.cat.name);
console.log(animals.cat.age);
```

```
const { animals: { dog, cat } } = person;
console.log(dog.name);
console.log(dog.age);
console.log(cat.name);
console.log(cat.age);
```

- Real Usecases :

```
// Node
const test = (req, res) => {
  const { body, params } = req;
}

// React
const Component = ({ keys, }) => [
]
```

- Array

- Before

```
const introduction = ["Hello", "I", "am", "Sarah"];
const greeting = introduction[0];
const name = introduction[3];

console.log(greeting, name);
```

- After

```
Hello Sarah  script.js:10
>
  1  // Object Destructuring
  2  // Array Destructuring
  3
  4  const introduction = ["Hello", "I", "am", "Sarah"];
  5  // const greeting = introduction[0];
  6  // const name = introduction[3];
  7
  8  const [greeting,,,name] = introduction;
  9
 10 console.log(greeting, name);
```

- First Class Functions

- A concept which tells that you can use functions as values

```
function abcd(a){
  a();
}

abcd(function(){console.log("hey")})
```

- This prints hey in the console

- Arrays Under the hood

- Arrays are also objects, stored in a key value pair format

```
var arr = [1,2,3,4];

arr = {
  0: 1,
  1: 2,
  2: 3,
  3: 4
}
```

- You can add -ve index in array as well, it will act as a key

- Higher Order Functions

- Accepting a function in parameters or returns a function, forEach is a higher order function.

```
function abcd(val){
}

abcd(function(){})
```

```
•  
function abcd(){  
    return function(){}  
}  
  
abcd()
```

- Constructor Functions

- Normal function where this is used and new keyword is used when it is called

```
function saanchaOfBiscuit(){  
    this.width = 12;  
    this.height = 22;  
    this.color = "brown";  
    this.taste = "sugary";  
}  
  
var bis1 = new saanchaOfBiscuit();  
var bis2 = new saanchaOfBiscuit();  
var bis3 = new saanchaOfBiscuit();
```

- Used when elements to be used have similar properties.

```
function circularButtonBanao(color){  
    this.radius = 2;  
    this.color = color;  
    this.icon = false;  
    this.pressable = true;  
}  
  
var redbtn = new circularButtonBanao("red");  
var greenbtn = new circularButtonBanao("green");
```

- IIFE : Immediately Invoked Function Expression

- Used to make Private Variables

```
.4  
.5 (function(){  
.6     var a = 12;  
.7 })()
```

- a here is a private variable, not available in DOM
- How to access

```
var ans = (function(){
    var privateval = 12;

    return {
        getter: function(){
            console.log(privateval);
        },
        setter: function(val){
            privateval = val;
        }
    }
})()
```

```
> ans.setter(24)
< undefined
> ans.getter()
24
< undefined
>
```

- Prototype :
 - Create an obj, followed by a dot operator
 - Every obj created get prototype property
 - It contains many helper properties to complete our tasks
 - for ex - .length property
- Prototype Inheritance :

- This is called Inheritance : properties of parents getting passed to children, this is also the case in JS.
- This is what is called prototypal inheritance in JS
- Base properties can be inherited and extra properties can be added.
 - `__proto__` is the way to inherit it

```
var human = {  
    canFly: false,  
    canTalk: true,  
    canWalk: true,  
    haveEmotions: true,  
    hasFourLegs: false  
}  
  
var sheryiansStudent = {  
    canMakeAmazingWebsite: true,  
    canMakeAwesomeAnimations: true,  
    canMakeWorldClassAwwwardedWebsites: true  
}  
  
sheryiansStudent.__proto__ = human;
```

- call apply bind
 - If you want to change where this points inside a function containing an object

- CALL

```
function abcd(){
  console.log(this.age);
}

var obj = {age: 24}

abcd.call(obj)
```

```
function abcd(val, val2, val3){
  console.log(this);
}

var obj = {age: 24}

abcd.call(obj,1,2,3)
```

- Apply : Array is passed instead of the direct parameter values
 - Usecase : To change the value to this

```
function abcd(val, val2, val3){  
    .... console.log(this, val, val2, val3);  
}  
  
var obj = {age: 24}  
  
abcd.apply(obj, [1,2,3])
```

- Bind : Bind will not run, but will give a function, can be stored in a var

```
function abcd(){  
    console.log(this);  
}  
  
var obj = {age: 24}  
  
var bindedfnc = abcd.bind(obj);  
bindedfnc();
```

- Pure and Impure Functions :

- Pure :

- It always returns same output for same input.
 - It will never change/update the value of a global variable.

```
function abcd(a,b){  
    return a*b;  
}  
I
```

```
var ans1 = abcd(1,2);  
var ans2 = abcd(1,2);
```

- Impure is just the opposite of pure

```
var abcdef = 12;  
  
function abcd(a,b){  
    abcdef = 24;  
    return a*b;  
}  
  
var ans1 = abcd(1,2);  
var ans2 = abcd(1,2);
```

-

```
function abcd(val){  
    return Math.random()*val;  
}  
  
var ans1 = abcd(2);  
var ans2 = abcd(2);
```

- Concurrency and Parallelism :
 - Concurrency : When sync code is running on Main stack and the async code on the side stack together.
 - Parallelism : This Focuses on making the task run on different processors and on their cores.
- Throttling : Controlling the number of executions of a code : ex - Scrolling
